Abstract

Introduction

To cope with real-world dynamics, an intelligent agent needs to incrementally acquire, update, accumulate, and exploit knowledge throughout its lifetime.

- **continual learning**, a foundation for AI systems to develop themselves adaptively. In a general sense, continual learning is explicitly limited by **catastrophic forgetting**, where learning a new task usually results in a dramatic performance degradation of the old tasks.

Abstract

Introduction

Learning is the basis for intelligent systems to accommodate environments. In response to external changes, evolution has empowered human and other organisms with strong adaptability to continually acquire, update, accumulate and exploit knowledge. Naturally we expect artificial intelligence (AI) systems to adapt in a similar way.

- This motivates the study of **continual learning**, where a typical setting is to learn a sequence of contents one by one and behave as if they were observed simultaneously. Such contents could be new skills, new examples of old skills, different environments, different contexts, etc., with particular realistic challenges incorporated.
- As the contents are provided incrementally over a lifetime, continual learning is also referred to as **incremental learning** or **lifelong learning** in much of the literature, without a strict distinction.

Unlike conventional machine learning models built on the premise of capturing a static data distribution, continual learning is characterized by learning from dynamic data distributions. A major challenge is known as **catastrophic forgetting**, where adaptation to a new distribution generally results in a largely reduced ability to capture old ones.

- This dilemma is a facet of the trade-off between **learning plasticity** and **memory stability**: an excess of the former interferes with the latter, and vice versa. A desirable solution for continual learning should obtain strong **generalizability** to accommodate distribution differences within and between tasks.
- A naive baseline, retraining all old training samples makes it easy to address the above challenges, but creates huge computational and storage overheads.

In fact, continual learning is primarily intended to ensure the **resource efficiency** of model updates, preferably close to learning only new samples.
